Methods

Summary

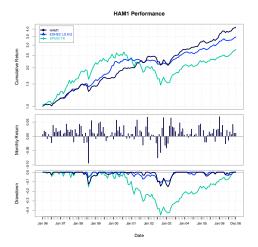

Appendix: Set Up PerformanceAnalytics

Overview

- Exploratory data analysis with finance data often starts with visual examination to:
 - examine properties of asset returns
 - compare an asset to other similar assets
 - compare an asset to one or more benchmarks
- Application of performance and risk measures can build a set of statistics for comparing possible investments
- Examples are developed using data for six (hypothetical) managers, a peer index, and an asset class index
- Hypothetical manager data was developed from real manager timeseries using accuracy and perturb packages to disguise the data while maintaining some of the statistical properties of the original data.

Draw a Performance Summary Chart.

- > charts.PerformanceSummary(managers[,c(manager.col,indexes.cols)],
- + colorset=rich6equal, 1wd=2, ylog=TRUE)

Show Calendar Performance.

Calculate Returns.

 The single-period arithmetic return, or simple return, can be calculated as

$$R_t = \frac{P_t}{P_{t-1}} - 1 = \frac{P_t - P_{t-1}}{P_{t-1}} \tag{1}$$

Simple returns, cannot be added together. A multiple-period simple return is calculated as:

$$R_t = \frac{P_t}{P_{t-k}} - 1 = \frac{P_t - P_{t-k}}{P_{t-k}} \tag{2}$$

The natural logarithm of the simple return of an asset is referred to as the continuously compounded return, or log return:

$$r_t = ln(1 + R_t) = ln\frac{P_t}{P_{t-1}} = p_t - p_{t-1}$$
 (3)

Calculating log returns from simple gross return, or vice versa:

$$r_t = ln(1 + R_t), R_t = exp(r_t) - 1.$$
 (4)

 Return.calculate or CalculateReturns (now deprecated) may be used to compute discrete and continuously compounded returns for data containing asset prices.

table.CAPM underlying techniques

Return.annualized — Annualized return using

$$prod(1 + R_a)^{\frac{scale}{n}} - 1 = \sqrt[n]{prod(1 + R_a)^{scale}} - 1$$
 (5)

▶ TreynorRatio — ratio of asset's Excess Return to Beta β of the benchmark

$$\frac{(\overline{R_a} - \overline{R_f})}{\beta_{a,b}} \tag{6}$$

- ActivePremium investment's annualized return minus the benchmark's annualized return
- Tracking Error A measure of the unexplained portion of performance relative to a benchmark, given by

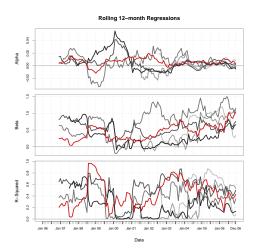

TrackingError =
$$\sqrt{\sum \frac{(R_a - R_b)^2}{len(R_a)\sqrt{scale}}}$$
 (7)

InformationRatio — ActivePremium/TrackingError

Compare to a Benchmark.

- > charts.RollingRegression(managers[, c(manager.col, peers.cols), drop =
 + FALSE], managers[, 8, drop = FALSE], Rf = .03/12, colorset = redfocus, 1wd =
- + FALSE], managers[, 8, drop = FALSE], Rf = .03/12, colorset = redfocus, 1wd = + 2)

Calculate Downside Risk.

Semivariance and Downside Deviation

 Downside Deviation as proposed by Sharpe is a generalization of semivariance which calculates bases on the deviation below a Minimumn Acceptable Return(MAR)

$$\delta_{MAR} = \sqrt{\frac{\sum_{t=1}^{n} (R_t - MAR)^2}{n}}$$
 (8)

- Downside Deviation may be used to calculate semideviation by setting MAR=mean(R) or may also be used with MAR=0
- Downside Deviation (and its special cases semideviation and semivariance) is useful in several performance to risk ratios, and in several portfolio optimization problems.

Value at Risk

- Value at Risk (VaR) has become a required standard risk measure recognized by Basel II and MiFID
- Traditional mean-VaR may be derived historically, or estimated parametrically using

$$z_c = q_p = qnorm(p) (9)$$

$$VaR = \bar{R} - z_c \cdot \sqrt{\sigma} \tag{10}$$

- Even with robust covariance matrix or Monte Carlo simulation, mean-VaR is not reliable for non-normal asset distributions
- For non-normal assets, VaR estimates calculated using GPD (as in VaR.GPD) or Cornish Fisher perform best
- Modified Cornish Fisher VaR takes higher moments of the distribution into account:

$$z_{cf} = z_c + \frac{(z_c^2 - 1)S}{6} + \frac{(z_c^3 - 3z_c)K}{24} + \frac{(2z_c^3 - 5z_c)S^2}{36}$$
(11)

$$modVaR = \bar{R} - z_{cf}\sqrt{\sigma}$$
 (12)

 Modified VaR also meets the definition of a coherent risk measure per Artzner, et. al. (1997)

Risk/Reward Ratios in PerformanceAnalytics

 SharpeRatio — return per unit of risk represented by variance, may also be annualized by

$$\frac{\sqrt[n]{prod(1+R_a)^{scale}} - 1}{\sqrt{scale} \cdot \sqrt{\sigma}}$$
 (13)

 Sortino Ratio — improvement on Sharpe Ratio utilizing downside deviation as the measure of risk

$$\frac{(\overline{R_a - MAR})}{\delta_{MAR}} \tag{14}$$

- Calmar and Sterling Ratios ratio of annualized return (Eq. 1) over the absolute value of the maximum drawdown
- Sortino's Upside Potential Ratio upside semdiviation from MAR over downside deviation from MAR

$$\frac{\sum_{t=1}^{n} (R_t - MAR)}{\delta_{MAR}} \tag{15}$$

 Favre's modified Sharpe Ratio — ratio of excess return over Cornish-Fisher VaR

$$\frac{(\overline{R_a - R_f})}{modVaR_{R_{n,0}}} \tag{16}$$

Summary

- Performance and risk analysis are greatly facilitated by the use of charts and tables.
- ► The display of your infomation is in many cases as important as the analysis.
- PerformanceAnalytics contains several tool for measuring and visualizing data that may be used to aid investment decision making.
- Further Work
 - Additional parameterization to make charts and tables more useful.
 - Pertrac or Morningstar-style sample reports.
 - Functions and graphics for more complicated topics such as factor analysis and optimization.

Install PerformanceAnalytics.

- ▶ As of version 0.9.4, PerformanceAnalytics is available in CRAN
- Version 0.9.5 was released at the beginning of July
- Install with:
 - > install.packages("PerformanceAnalytics")
- ► Required packages include Hmisc, zoo, and Rmetrics packages such as fExtremes.
- ▶ Load the library into your active R session using:
 - > library("PerformanceAnalytics").

Load and Review Data.

- > data(managers)
- > head(managers)
